

Abstract

Empowering Local Gastronomy: Development of a Web Platform for Galician Food Delivery

In the context of increasing digitalization in the food industry, many local restaurants still struggle to adopt affordable and functional online solutions, especially in regions like Galicia.

This project aims to design and implement a full-stack food delivery web application that enables small Galician restaurants to manage their digital presence, orders, and customer interactions while promoting regional gastronomy.

The application was developed using a modular architecture combining a Spring Boot backend with a MySQL database and a React frontend styled with TailwindCSS and managed via Redux. Development included five phases: backend setup, security and logic implementation using JWT, frontend integration, full-stack testing, and deployment using Docker and cloud services.

The final product supports role-based access, menu and ingredient management, cart and order processing, Stripe integration and secure authentication. Optional features such as recommendation systems are outlined for future development.

The platform meets its goals by offering an efficient, scalable, and user-friendly system tailored to local business needs, providing a viable alternative to mainstream food delivery platforms while reinforcing the visibility of Galician culinary culture.
